A: Try running from command line `pandoc -f markdown -t html -o filename.html filename.md` or PDF `pandoc -f pdf -t latex -o filename.pdf filename.md` HTML `pandoc -f html -t latex -o filename.html filename.md` Word `pandoc -f word -t latex -o filename.doc filename.md` As an alternative to the command line you can install pandoc in your Ubuntu/Debian repository (just search for it in the Software Center). This can be more convenient. There is another way, by using pandoc. Just do this, `pandoc -s -S./test.txt -t markdown -o output -s =>` Specify the output type(HTML/PDF/Word) as `markdown -S =>` Specify the file location as `test.txt` Q: Op-Amp's vs. non-linear resistor Is there any difference between an op-amp and a non-linear resistor? There are two different ways to look at this question. From a general point of view, a linear amplifier has the property that its output is linear, i.e. the output is proportional to the input. An ideal op-amp has a completely linear transfer function, which is a very useful property, but it has a limit, it cannot make sharp (steep) changes of output for small changes of input. However, the op-amp has other advantages that a non-linear resistor cannot have. The op-amp has an amplifier function, it can amplify an input signal and provide a gain. A resistor has no such gain. Another way to look at it is that the op-amp has a dynamic range that is significantly larger than a resistor. Both are voltage followers, but the op-amp can take care of more complex transfer functions. From the electrical point of view, an op-amp can do the job, but usually is more complicated than a resistor. It requires a small current in addition to the input signal. That current is necessary to maintain an op-amp in a stable, non-saturated state, for example. 82157476af
